# Supplemental Information for Use of DFT Distance Metrics for classification of SARS-CoV-2 Genomes

#### Micah Thornton and Monnie McGee

December 8, 2021

This document contains original research associated with the primary manuscript "Use of DFT Distance Metrics for Classification of SARS-CoV-2 Genomes". The enclosed results are referenced in the body of the manuscript, and offer further information about the primary results disclosed in the manuscript. This supplement is a PDF file that contains two sections, one with supplemental tables and associated descriptions, and one with supplemental figures and descriptions.

# 1 Supplemental Tables

Tables which contain further information, or are captured here for historical documentation of the evolution of the manuscript, are present in this section.

#### 1.1 Description of Distance Methods Compared

Below is a table which enumerates the classical post alignment techniques compared in the experimental section of the manuscript. The abbreviations used in Figure 3 of the manuscript are listed in column 2 of Table S1 as a guide to the methods being compared. In the analysis section of the manuscript there is a comparison of the pairwise distances that were produced from a set of distance calculation methods. The methods applied to the data set were from the R ape package [Paradis and Schliep, 2019]. These are described and the authors referenced and attributed in Table S1.

Table S1: Kinds of post-MSA Phylogenetic Comparisons

Method Name	Abbr.	Authors	Description
Transversions	TV	-	A count of the number of transver-
Count			sions, that is A or G to C or T
			mismatches in aligned sequences
Galatier-Gouy	GG96	Nicolas Galtier	A substitution model based ap-
		Manolo Gouy	proach which allows a time-varying
			coefficient for specific nucleotides.
			[Galtier and Gouy, 1995]
Transitions Count	TS	-	A count of the number of transi-
			tions counted, that is A to G or
			C to T mismatches in aligned se-
			quences
Barry-Hartigan	BH87	Daniel Barry	A distance that is asymetric,
		John A Hartigan	and treats each possible tran-
			sition/transversion differently
			[Barry and Hartigan, 1987]
Paralinear	paralin	James A. Lake	Uses an assymetric substitution
distance			model such as that used in the
			BH87 distance. [Lake, 1994]

MEGA	TN93	Koichiro Tamura	Specific kinds of transi-

Note, most of the data in Table S1 comes from the thorough documentation of the ape package in R [Paradis and Schliep, 2019] [R Core Team, 2021].

#### 1.2 Accuracy Metric Tables for Classification Procedures

In the manuscript, we utilize the genomic Fourier power spectra to classify viral sequences by their originating location. The accuracy table included here as Table S2 appeared in the original manuscript as Table 3. It was pointed out by reviewers that the overall accuracy metric which is reported in this situation is not the best metric to utilize due to the imbalance in the dataset (for instance, always guessing 'Europe' would produce an accuracy of 48%.). The manuscript has been updated to reflect this, and instead of accuracy, the F-measure is reported for each classifier.

Table S2: Five-fold Mean Cross Validation Accuracy and Binomial Confidence Intervals for classifiers trained with k-mer frequency vectors, and DFT power spectra vectors separately, for these approaches, all of the Fourier coefficients were used

Supervised Learner	k-mer Vectors (Interval)	DFT Power Spectra (Interval)
Naive Bayes	$0.42448 \ (0.41126, 0.43770)$	$0.59341 \; (0.58027, 0.60656)$
K-Nearest Neighbors (10)	$0.72226 \ (0.71028, 0.73425)$	$0.77595 \; (0.76479, 0.78710)$
Random Forest (500)	$0.65140 \ (0.63865, 0.66415)$	$0.80530 \; (0.79470, 0.81589)$
Neural Network(1 HL - 30 N)	$0.50537 \ (0.49199, 0.51875)$	$0.57981 \; (0.56661, 0.59302)$
Support Vector Machine	0.68790 (0.67551,0.70030)	$0.71152 \ (0.69940, 0.72365)$

Note that Table S2 (Previously Table 3 in the Manuscript) reports the overall five-fold cross validation accuracy of each of the classification procedures. Due to the imbalance of genomes assigned to geographic regions in the dataset, does not accurately display the superiority of the power spectra in classification tasks. Tables S3 and S4 contain the complete confusion matrices as well as class specific precision, recall, and F-measure for both the k-mer frequency vector method and the power spectra method.

# 2 Supplemental Figures

This section contains supplemental figures for the analysis that was performed and documented in the original manuscript.

### 2.1 Unsupervised Learning/Clustering Metrics

In the original manuscript we supply visualizations using T-SNE of the data in its power spectral representation and k-mer frequency representation, in addition to these, T-SNE plots are produced for two classical distances. Besides T-SNE plots which are displayed in Figure 1 of the primary manuscript, we also produced UMAP/PCA plots for the PS/k-mer methods which we show here in Figure S1.

Additionally, it was suggested that the validity of clusters formed from the power spectra should be assessed. We perform this analysis by inspecting the K-means clustering procedure results (using 25 different starting positions). Figure S2 A shows that the sum of squared error exhibits a knee with 8 clusters, which validates the use of 8 geographical regions for supervised learning. Figure S2 B shows a cluster plot for K-means with k = 8. The cluster plot does not show very clear delineations of clusters due to the imbalance in the data. From the silhouette plot (Figure S2 C), we can see that the clusters formed appear to be internally consistent with a few notable exceptions. For example, clusters 3 and 4 tend to blend together more than others. There was also one very small cluster found with only 4 elements, which indicated high internal

Table S3: Classification Results for Classification with various classifiers trained with the first five k-mer frequency vectors
